Introduction
This work was part of a broader study aimed at evaluating the carbon budget in a model wetland ecosystem, Mokré Louky (Wet Meadows) near Třeboň (Czech Republic). The work has focused on aboveground biomass production of Carex acuta, which dominates the vegetation in the unmanaged and permanently flooded part of the Wet Meadows.

Locality
The Wet Meadows is a flat depression of 450 ha. It is a marginal wetland located between the eastern edge of the town of Třeboň and Rožmberk fishpond. Most of the area is regularly mown and fertilized. The exception is the northernmost part of the Wet Meadows where there is no access for agricultural equipment owing to high water levels. This part of the Wet Meadows is covered with tall sedges such as Carex acuta and Carex vesicaria. Glyceria maxima grows in the wettest area near Rožmberk pond.

Methods
Destructive sampling was used to investigate the seasonal dynamics of aboveground biomass. The biomass was sampled repeatedly during the vegetation season in two- to four-week intervals. Five to nine successive harvests were taken in each of the six growing seasons studied (2006-2011).

Results and Discussion
Shoots of the spring cohort began to grow in late March (Graph 1). The tillers reached half of their length about day 150 (end of May) and their seasonal maximum length about day 210 (end of July). A similar dynamics was observed also for the growth in dry weight (Graph 2).

The seasonal maximum of aboveground biomass was 529 to 670 g.m⁻² (Graph 3). The highest seasonal maximum of aboveground biomass of Carex acuta (reaching 618 g.m⁻²) as well as the highest shoot density (553 m⁻²) was found in 2008, a year with rich but regular precipitation throughout the spring. Conversely, the highest seasonal maximum of aboveground biomass of accompanying species (346 g.m⁻²) was found in 2010, when precipitation was below the long-term average.

Conclusion
The aboveground production was stimulated by abundant precipitation in spring (in 2008). The proportion of accompanying species increased in dry years.
